CTZB ODDS v3 — SOLO TAGS

Ranked by EDGE, highest first — ties broken by sample size. UPSIDE = median best price reached. RISK = worst CLOSE between entry and the eventual peak.
v3 corrects the EDGE column. Every edge is now measured against that chart's OWN all-troughs rate. v2 used baselines set below the true rate — harmless on most charts, but the ETH 5D was listed at 70% when its real baseline is 84%, so every ETH 5D edge in v2 was overstated by 14 points.

Baselines (each chart's own all-troughs rate at 60 days, inside bull windows): **ETH 1D 69%** · **ETH 2D 69%** · **ETH 3D 71%** · **ETH 5D 84%** · **BTC 1D 72%** · **BTC 2D 72%**. Signal counts under 10 in red.

CONFLUENCE

One chart's tag confirmed by another chart within 10 days. GAIN is the lift over the SAME tag on the SAME chart without the confirmer — that is the only honest comparison, and because both arms are measured the same way, GAIN never depended on the baseline that v3 corrects. These figures are unchanged in substance from v2.

ALONE = the same tag on the same chart **without** the confirmer nearby. A high WIN with a low GAIN means the tag was already good. Counts under 12 in red. 560 combinations were computed; these are the best by GAIN, which is exactly the selection that produces false positives — read the last page.

HOW TO READ THIS

What changed in v3. The EDGE column was recomputed. A chart's baseline IS its all-troughs win rate, so an ALL TROUGHS row must show an edge of zero by definition. In v2 the ETH 5D ALL TROUGHS row showed 84% win and +14 edge, which was the tell: the 84% was the baseline. Inside a bull window **every** trough on the ETH 5D went 84% at 60 days, so no tag on that chart beats simply taking them all. ETH 5D "Any diamond" went from +14 to −1. ETH 3D, BTC 1D and BTC 2D shifted by 2 to 3 points. ETH 1D and ETH 2D are unchanged.

THE COLUMNS

UPSIDE	Median best price reached by that horizon. We take profit, so this is what was available — not the close at day 60.
RISK	The worst **close** between entry and the eventual peak. The most you were ever underwater before the trade worked. Measured on closes, so exchange wicks are excluded.
WORST	The single worst instance of RISK in that cell. One trade, not a median.
EDGE	Percentage points of win rate over that chart's own bull-window all-troughs rate. Zero means the tag told you nothing the chart did not.
GAIN	Confluence only. The lift over the SAME tag on the SAME chart without the confirmer.

WHAT TO TRUST

The cycle filter	The primary edge. Everything here is measured inside bull windows anchored to Bitcoin all-time highs, Window 4 from 2026-06-24. Outside those windows the tags are close to worthless.
Diamonds on the ETH 2D	89% at 60 days against a 69% baseline on 35 signals, 4.6 a year, risk −2.0%. Validated across RSI lengths 8 to 28 and pivot widths 2 to 5, so it is not fitted to the defaults. The single best cell in the study.
The ETH 5D as a CONFIRMER	Not as a chart to trade. A signal on one of the other five charts within 10 days of an ETH 5D trough went **82% with +41.3% upside**, against 63% and +23.6% outside that window — +18pp on n=1064. The strongest single effect in the stack, and it survived re-measurement. The 5D's own tags add nothing; its value is entirely as a clock for the other charts.
The prime dot	Stoch K between 20 and 50 at the trough. Pooled over nine charts, diamonds with the dot went 79% and +39.6% upside against 71% and +29.1% without. Positive at 10, 20, 30, 60 and 90 days and on 8 of 9 charts. XRP is the exception.
Bucket A	Strongest bucket on BTC and on the ETH 5D.

WHAT NOT TO TRUST

The top of the confluence table	560 combinations were computed and the page is sorted by the best of them. That is precisely how a false positive is manufactured. An earlier confluence finding on this data looked significant at p=0.003 and dissolved to p=0.42 when a longer file was supplied.
Anything under about 15 signals	Directional at best. Counts under 10 (solo) and 12 (confluence) are printed in red. Several cells rest on 3 to 8 trades.
Overlapping measurement	Signals on the 1D and 2D of one asset often describe the same market move, and the 60-day windows of consecutive signals overlap heavily. The effective sample is far smaller than the counts suggest.
GOLD over HOLLOW	The filled gold diamond is not the stronger glyph. Pooled over eight charts, excluding XRP, the HOLLOW diamond went 81% with +42.5% upside against the filled diamond's 72% and +31.4%. Hollow beat filled on 7 of 9 charts. XRP is the sole reversal. The colouring on the chart implies a ranking the data does not support.
The bucket boundaries	Move 40/55/65 by five points and which letter looks worst changes. A/B/C/D is vocabulary, not measurement. Bucket C is weakest at the current boundaries on most charts, but that is a property of where the lines sit.
Filters that were tested and dropped	Range expansion, volume, money flow, stochastic slope, stochastic level and the WGMI liquidity star all came back null or worse. The range expansion filter discarded a fifth of all diamonds and the discarded group had HIGHER upside (+38.5% vs +31.9%) and LOWER risk than the group it kept. It was removed from the indicator and the scanner in v9 / v6.
Intraday	The diamond carries no information below the daily. On ETH 4H and 12H it scores −3 to +2pp at every horizon.

Entry is the close of the confirmation bar, three pivot bars after the RSI low — six days on a 2D chart. The label sits on the trough; the bottom-row diamond marks the entry bar, and every figure here is priced from the entry bar. Data 2016–2026 for ETH, 2014–2026 for BTC, bull windows only. Past behaviour on historical data — not a forecast, not financial advice.
