# CTZB ODDS v4 — SOLO TAGS

**All figures are now measured under the LIVE regime** (BTC 2D CT RSI: bull after 8 bars at or above 60, bear after 12 bars at or below 40). Ranked by EDGE, ties broken by sample size.
The two grey columns on the right are the OLD hand-drawn-window figures, kept so you can see what changed. Those windows ended on known cycle tops, so they excluded the stretches that failed and every baseline sat about nine points too high. **The old win rates were not achievable in real time.** Trade the white columns.

Baselines, each chart's own all-troughs rate at 60 days inside the live regime: **ETH 1D 60%** (old 69%) · **ETH 2D 60%** (old 69%) · **ETH 3D 60%** (old 71%) · **ETH 5D 72%** (old 84%) · **BTC 1D 66%** (old 72%) · **BTC 2D 65%** (old 72%). Signal counts under 10 in red. A green win rate beat the old hand-drawn figure.

# CONFLUENCE

One chart's tag confirmed by another chart within 10 days, measured under the live regime. GAIN is the lift over the SAME tag on the SAME chart without the confirmer. Both arms are measured the same way, so GAIN never depended on the baseline.

ALONE = the same tag on the same chart **without** the confirmer nearby. Counts under 12 in red. 539 combinations were computed; these are the best by GAIN, which is exactly the selection that produces false positives — read the last page.

## WHAT THE VALIDATION FOUND

**The indicator passed both tests.** Every setting was frozen on data up to 31 Dec 2021 and scored on 2022–2026 untouched. The diamond edge went from +1pp in-sample to **+11pp out**. The ETH 5D window went from +14pp to **+39pp out**. The ETH 2D diamond went from 71% to **80%**. Nothing was re-tuned. Separately, the hand-drawn bull windows were replaced with a rule that could have been followed live, and the edge survived — it did not depend on hindsight.

**But the absolute win rates were inflated, and this sheet now says so.** The old windows ended on known cycle tops. They excluded exactly the stretches that failed, which lifted every baseline by roughly nine points. ETH 2D diamonds read 89% under those windows and **75% under a live rule** — same signals, honest measurement. Plan with the white columns.

| THE REGIME RULE | |
|---|---|
| **How it works** | Driven by BTC 2D CT RSI. **BULL** after 8 consecutive bars at or above 60. **BEAR** after 12 consecutive bars at or below 40. In between, the state holds — so an ordinary correction passes through the middle without flipping you. |
| **Why 8 bars for bull** | Every run of BTC 2D CT RSI at or above 60 was sorted by regime: runs of 8+ bars happened **27 times inside bull windows and zero times in a bear period**. The longest a bear ever held the zone was 7 bars. ETH 2D is the same. The test uses no return data, so the threshold is not fitted to P&L. |
| **Why the bear side is slower** | The mirror test does not separate. Runs of CT RSI at or below 40: 3+ bars is 20 bull / 16 bear, 8+ bars is 4 / 8, 12+ bars is 2 / 6. Bull markets dip into the bear zone constantly, so a brief visit means nothing. 12 bars is the shortest length where bear periods clearly dominate. |
| **Why not combine with the halving** | Tested. Requiring both gave 89% win and +103.8% upside in-sample and **50% on 20 signals out of sample**. Textbook overfitting. One rule or the other, never both. |

# HOW TO READ THIS

## THE COLUMNS

| | |
|---|---|
| **UPSIDE** | Median best price reached by that horizon. We take profit, so this is what was available — not the close at day 60. |
| **RISK** | The worst **close** between entry and the eventual peak. Measured on closes, so exchange wicks are excluded. |
| **EDGE** | Percentage points of win rate over that chart's own all-troughs rate in the live regime. Zero means the tag told you nothing the chart did not. |
| **old WIN / old EDGE** | The same cell under the hand-drawn windows. Reference only. Do not plan with these. |
| **GAIN** | Confluence only. The lift over the SAME tag on the SAME chart without the confirmer. |

## WHAT TO TRUST

| | |
|---|---|
| **The regime filter** | The primary edge, and it is not hindsight. Pooled diamonds score +9 edge under a live rule and **+1 with no regime filter at all**. That last number is the most important in the study: strip the filter and the diamond is worth nothing. |
| **Diamonds on the ETH 2D** | 75% live on 36 signals, +46.5% upside, risk −2.3%. Validated across RSI lengths 8 to 28 and pivot widths 2 to 5, so not fitted to the defaults. Still the best cell in the study. |
| **The ETH 5D as a CONFIRMER** | Not as a chart to trade. A signal on another chart within 10 days of an ETH 5D trough lifted the win rate **+39pp out of sample**. It also holds with no regime filter at all, so it does not depend on the cycle call. The strongest and most robust effect in the stack. |
| **The prime dot** | Stoch K between 20 and 50 at the trough. Flat in-sample, **+16pp out of sample** on ETH and BTC diamonds with upside more than doubled. Promoted to its own glyph and alert in v11. |

## WHAT NOT TO TRUST

| | |
|---|---|
| **The old win rates** | Every figure in the grey columns assumed windows that ended on known cycle tops. Roughly nine points of that was hindsight. |
| **The top of any sorted table** | 539 confluence combinations were computed and the page is sorted by the best. That is how a false positive is manufactured. Worse: the #1 and #2 tags on the 2021 leaderboard were the **worst** performers afterwards, while the ETH 2D diamond ranked only 4th. Trade the structural effects, not the top row. |
| **Anything under about 15 signals** | Directional at best. Counts under 10 (solo) and 12 (confluence) are in red. Several cells rest on 3 to 8 trades. |
| **Overlapping measurement** | Signals on the 1D and 2D of one asset often describe the same move, and consecutive 60-day windows overlap heavily. The effective sample is smaller than the counts suggest. |
| **GOLD versus HOLLOW** | Earlier versions of this sheet said the hollow diamond was the stronger glyph. **That failed out of sample** — hollow led by +10pp before 2022 and trailed by 1pp after. Neither glyph reliably leads. The claim has been removed. |
| **The bucket boundaries** | Move 40/55/65 by five points and which letter looks worst changes. A/B/C/D is vocabulary, not measurement. Bucket C is weakest at the current boundaries — 59% out of sample — but that is a property of where the lines sit. |
| **Filters tested and dropped** | Range expansion, volume, money flow, stochastic slope, stochastic level and the WGMI liquidity star all came back null or worse. The range expansion filter discarded a fifth of all diamonds and the discarded group had HIGHER upside. |
| **Intraday** | The diamond carries no information below the daily. On ETH 4H and 12H it scores −3 to +2pp at every horizon. |
| **The 5D mechanism** | Unexplained. The same test with a BTC 5D confirmer shows nothing (p=1.00). Promising, not proven. |

Entry is the close of the confirmation bar, three pivot bars after the RSI low — six days on a 2D chart. The label sits on the trough; the bottom-row diamond marks the entry bar, and every figure here is priced from the entry bar. Data 2016–2026 for ETH, 2014–2026 for BTC. Matches CT Zone Bounce v11 and CTZB Scanner v8. Past behaviour on historical data — not a forecast, not financial advice.
